

## Clinical Policy: Digital EEG Spike Analysis

Reference Number: PA.CP.MP.105

Effective Date: 06/18

Last Review Date: 06/2020

[Coding Implications](#)

[Revision Log](#)

### Description

Electroencephalography (EEG) is a significant component of epilepsy diagnosis, along with a thorough medical history and neurological workup. Most EEGs today are performed on digital machines which record data and automatically detect spikes that may indicate seizures (ACNS, 2008). For the purpose of this policy, digital EEG spike analysis, which also is known as 3D dipole localization or dipole source imaging, refers to additional analysis of digitally recorded EEG spikes by a technician and a physician. Digital EEG spike analysis is also called 3D dipole localization or dipole source imaging.

### Policy/Criteria

- I. It is the policy of PA Health & Wellness (PHW), that digital EEG spike analysis, including topographic voltage and/or dipole analysis, is **medically necessary** for the presurgical evaluation of members with intractable epilepsy, in conjunction with video EEG long-term monitoring.
  
- II. It is the policy of PHW that digital EEG spike analysis is **not medically necessary** for any other indication.

### Background

According to the American Clinical Neurophysiology Society's (ACNS) Guidelines for Long Term Monitoring of Epilepsy, digital EEG is the industry standard (2008). Ambulatory EEG, video EEG, and routine EEG all use digital technology and usually incorporate automatic spike detection. A report by the American Academy of Neurology (AAN) and the ACNS states that multiple well-designed studies have established automatic spike and seizure detection via digital EEG as highly sensitive, though not very specific (1997, p. 280). This is also true of EEG in general. There are several reasons that an EEG would record a false positive, and most EEG patterns can be caused by a wide variety of neurologic conditions, while many diseases can produce more than one type of EEG pattern (Moeller, Haider & Hirsch, 2015). Nonetheless, the AAN recommends EEG with automatic seizure and spike detection in clinical practice, commenting that "general clinical use in the community has been very positive" (AAN & ACNS, 1997). Automatic spike detection can save a great amount of time as a technician or electroencephalographer does not have to visually review hours or days of data. However, there are some circumstances in which further analysis of the EEG is required, beyond the automatic digital spike analysis.

The ACNS states that in general, 3D dipole localization would require an extra hour of work by a technician, and 20-30 minutes of physician time to review the technician's work and data produced. Moreover, digital EEG analysis by 3D dipole localization is an advanced procedure that is most commonly used at epilepsy surgery centers, where staff are familiar with how to perform it. The AAN and ACNS recommend further digital analysis, in conjunction with review

**CLINICAL POLICY**

by a technician or provider, in the noninvasive evaluation of candidates for epilepsy surgery (AAN & ACNS, 1997, p. 281). They note that:

“The well-designed studies of this specific technique [dipole analysis] are few but consistent and confirmed in follow-up postoperatively. The clinical rationale seems clear. Control testing for evoked potential known cortical generator sites has confirmed the technical accuracy of dipole localization. The use of dipole analysis seems sufficiently demonstrated to warrant its clinical use in patients undergoing evaluation for surgical therapy for epilepsy. In other clinical settings, it has not been demonstrated to be sufficiently clinically useful to warrant general clinical use at this time” (AAN & ACNS, 1997, p. 280).

It is important to note that the ACNS specifically states that ambulatory EEG is not appropriate for “detailed characterization of EEG features as is required in presurgical evaluation” (ACNS, 2008, p. 15).

3D spike dipole source analysis, or digital EEG spike analysis, has been shown to be concordant with other modes of presurgical evaluation of epilepsy, including a thorough neurological workup with video EEG, magnetic resonance imaging (MRI), and multiple other imaging and neuropsychological tests; electrocorticography; and magnetoencephalography (Park et al., 2015). Furthermore, Park and others cite three other studies demonstrating “that dipole source models can be successfully employed to detect the epileptogenic foci of interictal epileptiform discharges” (2015). Park and others agree with the AAN and ACNS that digital EEG spike analysis is “recommended for the presurgical evaluation of intractable epilepsy patients (2015).

**Coding Implications**

This clinical policy references Current Procedural Terminology (CPT®). CPT® is a registered trademark of the American Medical Association. All CPT codes and descriptions are copyrighted 2020, American Medical Association. All rights reserved. CPT codes and CPT descriptions are from the current manuals and those included herein are not intended to be all-inclusive and are included for informational purposes only. Inclusion or exclusion of any codes in this policy does not guarantee coverage. Providers should reference the most up-to-date sources of professional coding guidance prior to the submission of claims for reimbursement of covered services.

| CPT®*<br>Codes | Procedure codes that support medical necessity criteria  |
|----------------|--|
| <b>95957</b>   | <b>Digital EEG spike analysis</b> when performed in conjunction with any of the following:   |
| 95718          | Electroencephalogram (EEG), continuous recording, physician or other qualified health care professional review of recorded events, analysis of spike and seizure detection, interpretation and report, 2-12 hours of EEG recording; with video (VEEG)  |
| 95720          | Electroencephalogram (EEG), continuous recording, physician or other qualified health care professional review of recorded events, analysis of spike and seizure detection, each increment of greater than 12 hours, up to 26 hours of EEG recording; interpretation and report after each 24-hour period; with video (VEEG) |
